

Import Data using Transform Maps (Spreadsheet)

Phase 3 – Project Design

Introduction

The Project Design Phase defines how the proposed import solution will work. The design describes the flow of spreadsheet data through ServiceNow and explains the relationship between the source file, Import Set, Transform Map, field mappings, and target table.

System Architecture

The basic architecture is: Spreadsheet → Import Set → Import Set Table → Transform Map → Target ServiceNow Table. The spreadsheet is the source. The Import Set provides a temporary area for imported source rows. The Transform Map controls transformation and field mapping. The target table stores final records.

Data Flow Design

First, the user prepares the spreadsheet. Next, the file is imported into ServiceNow. Source columns become available for mapping. The Transform Map connects each required source field to its corresponding target field. When transformation runs, source values are processed and written to target records.

Field Mapping Design

Field mapping is a major part of the design. For example, a source column named Name may map to a target field that stores a name value. A source column such as Email should be connected to the appropriate email field. Exact mappings depend on the selected target table.

Transform Map Design

The Transform Map contains rules that tell ServiceNow how to transform imported data. It identifies source and target tables and provides field maps. If required, transformation scripts or conditions can be used for data needing special processing.

Data Validation Design

The design should include checks for empty required values, incorrect formats, unexpected text, duplicate identifiers, and missing mappings. Validation is important because successful import does not automatically mean every value is logically correct.

Error Handling Design

Rows that fail validation or transformation should be reviewed through import and transformation results. Common causes include missing required values, incorrect formats, or mapping mistakes. The project documentation should record common issues and corrections.

Design Output

The main output is a clear workflow and mapping plan. The design provides a foundation for planning project activities and implementing the import process in ServiceNow.
