

Import Data using Transform Maps (Spreadsheet)

Phase 5 – Project Development

Introduction

Project Development is the implementation stage where the planned design is converted into a working ServiceNow import workflow. Development starts with source data preparation and continues through Import Set creation, Transform Map configuration, field mapping, transformation, and result verification.

Spreadsheet Preparation

The spreadsheet is prepared with clear column names and sample records. Data should be consistent and easy to understand. Empty rows and unnecessary columns should be removed. The file should be saved in a supported format before import.

Importing the Spreadsheet

The prepared spreadsheet is imported into ServiceNow using the appropriate import process. ServiceNow receives the source data and makes it available for transformation. Imported rows are stored in the Import Set area so transformation can be performed in a controlled manner.

Import Set Configuration

The Import Set provides the temporary representation of source data. During development, imported columns are reviewed to ensure expected source values are available. If the source structure is incorrect, the spreadsheet should be corrected and imported again.

Transform Map Configuration

The Transform Map is configured by selecting appropriate source and target tables. The map establishes the relationship between imported source fields and target fields. This is the central configuration used to convert spreadsheet rows into target records.

Field Mapping

Each required source field is mapped to its corresponding target field. Mapping should be checked carefully because an incorrect mapping can place information into the wrong field. Special processing can be added where needed.

Running the Transformation

After the Transform Map is configured, the transformation is executed. ServiceNow processes imported rows and attempts to create or update target records. Transformation results should be reviewed for successful rows and errors.

Development Verification

Development is successful when spreadsheet data reaches the target table with expected values and structure. Configuration steps should be recorded so the same process can be reproduced during testing and demonstration.
